

Overview

Network engineers are always looking for ways to automate the tasks of maintaining network devices. Logging into network devices to make changes or to upgrade software is tedious, time consuming, and prone to errors. Creating interactive scripts takes the monotony out of maintaining network devices. This document will show how easy it is to create and run CCS scripts. For more detailed information, please review the Infoblox CCS Scripting Guide.

Anatomy of a CCS script

A CCS script consists of several required statements:

- **Script:** This is the name of your script. For example, 'Script: Set up routing'.
- **Script-Filter:** This statement defines the devices that the script will run on. For example, 'Script-Filter: \$Vendor eq "Cisco" and \$Model in ["2811", "2821", "871", "2621XM"]'. \$Vendor and \$Model in this example are well known attributes. In simple English, this statement translates to 'run this script only on cisco 2811, 2821, 871, and 2621XM devices.
- **Action:** This is the name of the action. After naming your script and defining the devices, what do you want to do on these devices? For example, 'Action: set router statement' is the name of this action
- **Action-Commands:** This is the command or series of commands that you want to run on the devices. For example, 'Action-Commands: show vlan'. This means the command 'show vlan' will be run.

A CCS script can have the following optional statements:

- **Script Section**
 - Script-Description
 - Script-Variables
 - Script-Timeout
 - Script-Login
- **Action Section**
 - Action-Description
 - Action-Filter
 - Action-Timeout
 - Output-Triggers
- **Issue Section**
 - Issue-ID
 - Issue-Severity
 - Issue-Template
 - Issue-Filter
 - Issue-Details
 - Issue-Variables
 - Issue-Description
- **Trigger Section**
 - Trigger
 - Trigger-Template
 - Trigger-Commands
 - Trigger-Filter
 - Trigger-Variables
 - Trigger-Description
 - Output-Triggers

Please review the Infoblox CCS Scripting Guide for more information on the above optional statements

Below is a simple script

Script: Show vlans

Script-Filter: \$Vendor eq "Cisco" and \$Model eq "catalyst3560v248ps"

Action: showing vlans

Action-Commands: show vlan

When you run this script, this is what you see:

Job Details Viewer Connections: **sw2 (10.60.16.5) [Primary]** ▼

Job Detail ID: 12
Job ID: 12 **Start Time:** 2014-01-03 09:52:07
Script: showing vlans on thomas switch **End Time:** 2014-01-03 09:52:15
Device: sw2 ([10.60.16.5](#)) **Status:** ✔ OK

```

-----
# DO NOT EDIT. This script is maintained by the job specification
# system. Changing the actual script in the vault or the job
# specification will alter the contents of this copy of the script
# causing a loss of any changes made to the script. In addition,
# modifying the script file directly will violate any job approval
# mechanism in place.
-----
Script: showing vlans on thomas switch
Script-Description: 'showing vlans on thomas' switch'
Script-Groups:
  MyNetwork: thomas' switch
-----
Script-Filter: $Vendor eq "Cisco" and $Model eq "catalyst3560v248ps"

Action: showing vlans

Action-Commands: show vlan
  
```

The script tab shows the script

Job Details Viewer Connections: **sw2 (10.60.16.5) [Primary]** ▼

09:52:07 Script-Filter
 09:52:07 ✔ Filter matches
 09:52:07 \$Vendor eq "Cisco" and \$Model eq "catalyst3560v248pe"

1. Action: 'showing vlans'

09:52:10 Action-Commands
 09:52:10 ✔ show vlan

The process log tab shows script running. The process log allows you to monitor how well the script ran. If there are any errors that arise during the script run, they would appear here. The check marks show successful execution of each step. In the filter match, the vendor name and model name are case sensitive. You can ensure proper case by looking at the inventory listing for the device.

20   VLAN0020                active
21   VLAN0021                active
26   VLAN0026                active
28   VLAN0028                active
30   VLAN0030                active
39   VLAN0039                active
40   VLAN0040                active
41   VLAN0041                active
```

The session tab shows running of the script from the telnet or SSH session. This session is the same as a manual telnet or SSH session to run the same command.

Let's look at a more complex script that has user input:

Script-Filter:

`$Vendor eq "Cisco" and $sysDescr like /IOS/`

Script-Variables:

`$username` word "UserName"
`$password` password "New Password"

Action:

Set IOS User Password

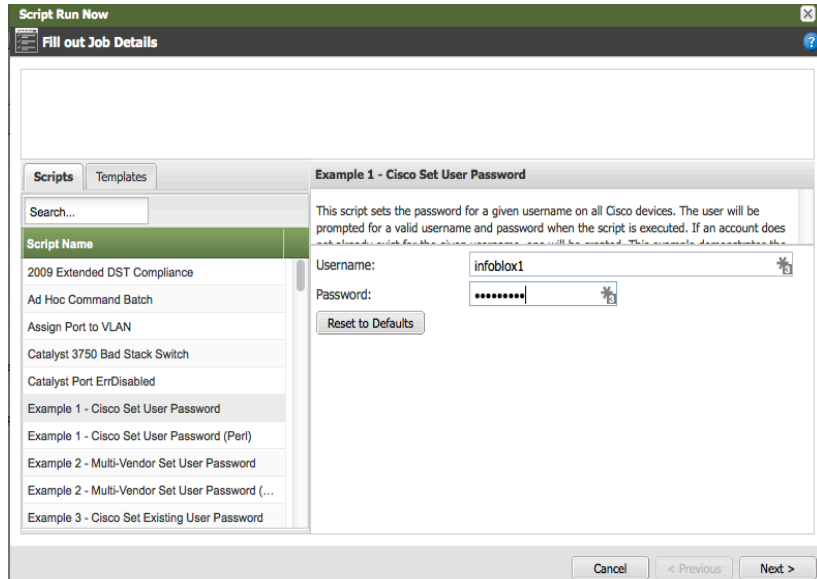

Action-Description:

This action is executed once for every device that matches the Script-Filter defined above. It sets the password for the given user account and then saves the configuration.

Action-Commands:

```
config terminal
username $username password 0 $password
exit
write memory
```

When you run this script, this is what you see:

When you run the script, it requests input for the username and password. This input is the result of the definitions of the script variables `$username` and `$password`. The username is defined as type "word", which means any string without whitespace can be entered. The password is defined as type "password", which means any string can be entered, however only stars will be displayed. The "UserName" and "Password" fields define the GUI prompts to be displayed to the user when the script is executed.
